Calculating momentum

MIT | Academy of Engineering

(An Autonomous Institute Affiliated to Savitribai Phule Pune University)

Write a program that accepts the mass of an object (in kilograms) and its velocity (in meters per second), then calculates and displays the momentum of the object. The momentum p is calculated using the formula:p=m XU where: m is the mass of the object (in kilograms). v is the velocity of the object (in meters per second).

Input Format: A single floating-point number representing the mass of the object in kilograms. A single floating-point number representing the velocity of the object in meters per second. Output Format: The output will display calculated momentum with appropriate units (kgm/s) (rounded up to 2 decimal places).

Page 2 / 20

Program :

```python
# Calculating momentum
M = float(input("Enter mass (in Kg) : "))
V = float(input("Enter velocity (in m/s) : "))
momentum = M*V
print(f"Momentum = {momentum:.2f} Kgm/s")
```

Output :

```
Enter mass (in Kg) : 2.4
Enter velocity (in m/s) : 23.413
Momentum = 56.19 Kgm/s
```
